Databases and Queries

Information are stored in databases and used to answer queries.

A cooking website that offers recipes.

What can I cook with tomato and eggplant?

IMDB stores information about movies.

In which movies can we see these two actors?

The schedule of your dentist.

Can I have a 2-hour consultation on a Monday?

The goal is always to compute the answer efficiently!

Formalization part 1: Databases as relational structures

Schema : $\sigma := \{P_{(1)}, R_{(2)}, S_{(3)}\}$

A *relational structure* D :

<i>P</i>
France
USA
Germany
Poland

<i>R</i>			
Paris	France		
Bourg-la-Reine	France		
Houston	USA		
Meudon	France		
Warsaw	Poland		

<i>S</i>		
Alexandre	Bourg-la-Reine	Warsaw
Sophie	Bourg-la-Reine	Meudon
Tim	Bourg-la-Reine	Bourg-la-Reine
Jack	Houston	Houston
Julie	Paris	Paris

Formalization part 2: Queries written in first-order logic

What are all of the countries?

$$q(x) := P(x)$$

Is there someone who works and lives in the same city?

$$q() := \exists x \exists y S(x, y, y)$$

What are the pairs of cities that are in the same country?

$$q(x, y) := \exists z R(x, z) \wedge R(y, z)$$

Who are the people who do not work where they live?

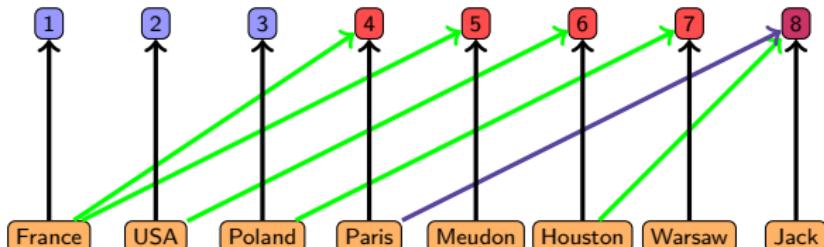

$$q(x) := \exists y \exists z S(x, y, z) \wedge y \neq z$$

Which cities satisfy: everybody who lives there works there too?

$$q(x) := \forall y \forall z S(y, x, z) \implies z = x$$

Formalization part 3: Databases as graphs

P
France
USA
Italy

R

Paris	France
Meudon	France
Houston	USA
Rome	Italy

S

Jack	Houston	Paris
------	---------	-------

P(x) becomes $\exists w, \text{Blue}(w) \wedge \mathbf{B}(x, w)$

R(x,y) becomes $\exists w, \text{Red}(w) \wedge \mathbf{B}(x, w) \wedge \text{G}(y, w)$

S(x,y,z) becomes $\exists w, \text{Purple}(w) \wedge \mathbf{B}(x, w) \wedge \text{G}(y, w) \wedge \text{V}(z, w)$

$\exists x \dots$ becomes $\exists x, \text{Orange}(x) \wedge \dots$

$\forall x \dots$ becomes $\forall x, \text{Orange}(x) \Rightarrow \dots$

Computing the whole set of solutions?

In general:

Database: $\|D\|$ the size of the database.

Query: k the arity of the query.

Solutions: Up to $\|D\|^k$ solutions!

Practical problem:

A set of 50^{10} solutions is not easy to store / display!

Theoretical problem:

The time needed to compute the answer does not reflect the hardness of the problem.

Can we do anything else instead?

Other problems

Model-Checking : Is this true ?

Input:

\mathbf{D}, q

Goal:

Yes or NO? $\mathbf{D} \models q$?

Ideally:

$O(\|\mathbf{D}\|)$

Testing : Is this tuple a solution ?

Counting : How many solutions ?

Enumeration : Enumerate the solutions

Other problems

Model-Checking : Is this true ?

Testing : Is this tuple a solution ?

Input:

\mathbf{D}, q, \bar{a}

Goal:

Test whether $\bar{a} \in q(\mathbf{D})$.

Ideally:

$O(1) \circ O(\|\mathbf{D}\|)$

Counting : How many solutions ?

Enumeration : Enumerate the solutions

Other problems

Model-Checking : Is this true ?

Testing : Is this tuple a solution ?

Counting : How many solutions ?

Input:

\mathbf{D}, q

Goal:

Compute $|q(\mathbf{D})|$

Ideally:

$O(\|\mathbf{D}\|)$

Enumeration : Enumerate the solutions

Other problems

Model-Checking : Is this true ?

Testing : Is this tuple a solution ?

Counting : How many solutions ?

Enumeration : Enumerate the solutions

Input:

\mathbf{D}, q

Goal :

Compute 1st sol, 2nd sol, ...

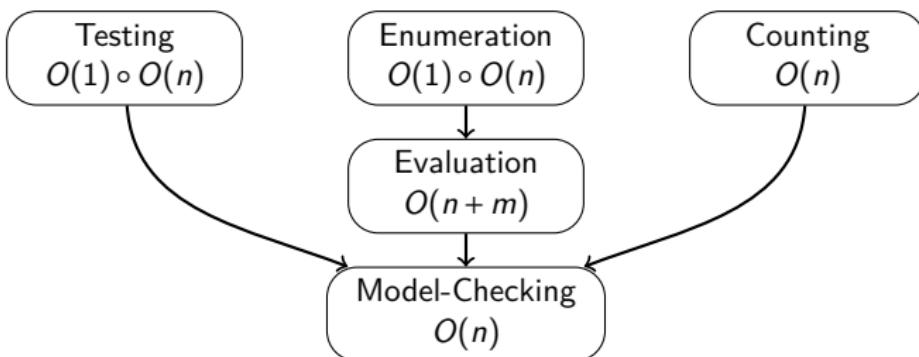

Ideally:

$O(1) \circ O(\|\mathbf{D}\|)$

Comparing the problems

For FO queries over a class \mathcal{C} of databases.

	Ideal running time
Model-Checking : Is this true ?	$O(n)$
Testing : Is this tuple a solution ?	$O(1) \circ O(n)$
Counting : How many solutions ?	$O(n)$
Enumeration : Enumerate the solutions	$O(1) \circ O(n)$
Evaluation : Compute the entire set	$O(n + m)$

Algorithms

oooo
○○○○○○○

Conclusion

oooo

Query enumeration

Input : $\|\mathbf{D}\| := n$ & $|q| := k$ (computation with RAM)

Goal : output solutions one by one (no repetition)

STEP 1: Preprocessing

Prepare the enumeration : Database $D \rightarrow$ Index I

Preprocessing time : $f(k) \cdot n \rightsquigarrow O(n)$

STEP 2 : Enumeration

The enumerate : Index $I \rightarrow \overline{x_1}, \overline{x_2}, \overline{x_3}, \overline{x_4}, \dots$

Delay : $O(f(k)) \rightsquigarrow O(1)$

Constant delay enumeration after linear preprocessing

$O(1) \circ O(n)$

Properties of efficient enumeration algorithms

Mandatory:

- First solution computed in time $O(\|\mathbf{D}\|)$.
- Last solution computed in time $O\left(\|\mathbf{D}\| + |q(\mathbf{D})|\right)$.
- No repetition!

Optional:

- Enumeration in lexicographical order.
- Use a constant amount of memory.

(1,6)

⋮

(4,5)

(4,7)

(4,8)

⋮

(n,n)

Example 1

- Database $\mathbf{D} := \langle \{1, \dots, n\}; E \rangle \quad \| \mathbf{D} \| = |E|$
- Query $q_1(x, y) := E(x, y)$

E

(1,1)

(1,2)

(1,6)

⋮

(4,5)

(4,7)

(4,8)

⋮

(n,n)

For the enumeration problem

Preprocessing: nothing

Enumeration: read the list.

For the counting problem

Computation: go through the list

Answering: output the result.

For the testing problem

Harder than it looks!

Dichotomous research? $O(\log(\| \mathbf{D} \|))$.

Example 2

- Database $D := \langle \{1, \dots, n\}; E \rangle$ $\|D\| = |E|$
- Query $q_2(x, y) := \neg E(x, y)$

E

(1,6)

⋮

(2,3)

⋮

(i,j)

(i,j+1)

(i,j+3)

⋮

(n,n)

For counting problem

Computation: Do the same algorithm!

Answering: $|q_2(D)| = n^2 - |q_1(D)|$

For the testing problem

Same difficulty!

$\bar{a} \in q_2(D) \iff \bar{a} \notin q_1(D)$

For the enumeration problem

We need something else!

Compute the set of solutions

=

Boolean matrix multiplication

$$\begin{pmatrix} E_1(1,1) & \dots & E_1(1,i) & \dots & E_1(1,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ E_1(x,1) & \dots & E_1(x,z) & \dots & E_1(x,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ E_1(n,1) & \dots & E_1(n,z) & \dots & E_1(n,n) \end{pmatrix}$$

 $A : \text{Adjacency matrix of } E_1$ $C : \text{Result matrix}$ $B : \text{Adjacency matrix of } E_2$

$$\begin{pmatrix} q(1,1) & \dots & q(1,y) & \dots & q(1,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ q(x,1) & \dots & q(x,y) & \dots & q(x,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ q(n,1) & \dots & q(n,y) & \dots & q(n,n) \end{pmatrix}$$

Example 3

- Database $D := \langle \{1, \dots, n\}; E_1, E_2 \rangle \quad \|D\| = |E_1| + |E_2| \quad (E_i \subseteq D \times D)$
- Query $q(x, y) := \exists z, E_1(x, z) \wedge E_2(z, y)$

 $B : \text{Adjacency matrix of } E_2$

$$\begin{pmatrix} E_2(1,1) & \dots & E_2(1,y) & \dots & E_2(1,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ E_2(z,1) & \dots & E_2(z,y) & \dots & E_2(z,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ E_2(n,1) & \dots & E_2(n,y) & \dots & E_2(n,n) \end{pmatrix}$$

- Linear preprocessing: $O(n^2)$
- Number of solutions: $O(n^2)$
- Total time: $O(n^2) + O(1) \times O(n^2)$
- Boolean matrix multiplication in $O(n^2)$

$$\begin{pmatrix} E_1(1,1) & \dots & E_1(1,i) & \dots & E_1(1,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ E_1(x,1) & \dots & E_1(x,z) & \dots & E_1(x,n) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ E_1(n,1) & \dots & E_1(n,z) & \dots & E_1(n,n) \end{pmatrix}$$

$A : \text{Adjacency matrix of } E_1$

 $C : \text{Result matrix}$

Conjecture: "There are no algorithm for the boolean matrix multiplication working in time $O(n^2)$."

Example 3

- Database $D := \langle \{1, \dots, n\}; E_1; E_2 \rangle \quad \|D\| = |E_1| + |E_2| \quad (E_i \subseteq D \times D)$
- Query $q(x, y) := \exists z, E_1(x, z) \wedge E_2(z, y)$

This query cannot be enumerated with constant delay¹

We need to put restrictions on queries and/or databases.

¹Unless there is a breakthrough with the boolean matrix multiplication.

What kind of restrictions?

No restriction on the database part

Only works for a **strict** subset of ACQ

Bagan, Durand, Grandjean

Highly expressive queries
(MSO queries)

Only works for trees
(graphs with bounded tree width)

Courcelle, Bagan, Segoufin,
Kazana

FO queries

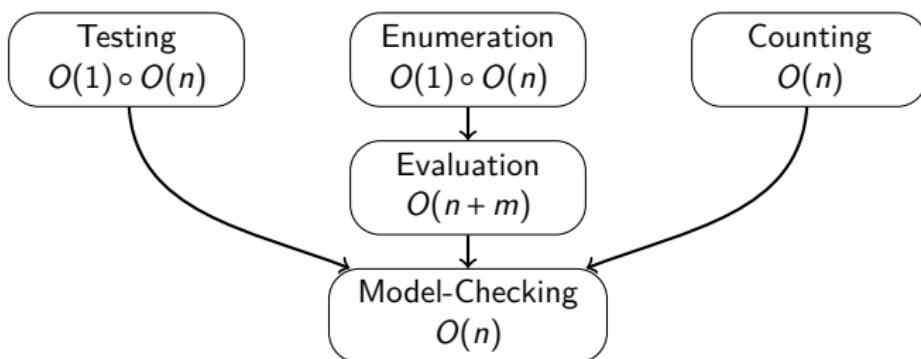

This talk!

Comparing the problems

Classes of graphs

Classes of graphs

Nowhere dense graphs

Defined by Nešetřil and Ossona de Mendez.¹

Examples:

- Graphs with bounded degree
- Graphs with bounded tree-width
- Planar graphs
- Graphs that exclude a minor

Can be defined using:

- An ordering of vertices with good properties
- A winning strategy for some two player game

Definition with a game

Definition : (ℓ, r) -Splitter game¹

A graph G and two players, Splitter and Connector.

Each turn:

Connector picks a node c

Splitter picks a node s

$$G := N_r^G(c) \setminus s$$

If in less than ℓ rounds the graph is empty, Splitter wins.

¹Grohe, Kreutzer, Siebertz STOC '14

Definition with a game

Definition : (ℓ, r) -Splitter game¹

A graph G and two players, Splitter and Connector.

Each turn:

Connector picks a node c

Splitter picks a node s

$$G := N_r^G(c) \setminus s$$

If in less than ℓ rounds the graph is empty, Splitter wins.

Theorem¹

\mathcal{C} nowhere dense $\iff \exists f_{\mathcal{C}}, \forall G \in \mathcal{C}, \forall r \in \mathbb{N}:$

Splitter has a winning strategy for the $(f_{\mathcal{C}}(r), r)$ -splitter game on G .

Splitter game on cliques

We have a clique of size $n-1$.

If the number of rounds $<$ size of the clique, Splitter loses.

For $r = 1, \forall \ell \in \mathbb{N}$ there is a clique G :

Connector wins the $(\ell, 1)$ -splitter game on G .

Results

Theorem: Schweikardt, Segoufin, Vigny (PODS '18)

Over *nowhere dense* classes of graphs, for every FO query, after a *pseudo-linear* preprocessing, we can:

- **enumerate** every solution with constant delay.
- **test** whether a given tuple is a solution in constant time.

Theorem: Grohe, Schweikardt (alternative proof, Vigny)

Over *nowhere dense* classes of graphs, for every FO query, we can **count** the number of solutions in *pseudo-linear* time

Pseudo-linear?

Definition

An algorithm is pseudo linear if:

$$\forall \epsilon > 0, \quad \exists N_\epsilon : \quad \begin{cases} \|G\| \leq N_\epsilon \implies \text{Brut force: } O(1) \\ \|G\| > N_\epsilon \implies O(\|G\|^{1+\epsilon}) \end{cases}$$

Examples: $O(n)$, $O(n \log(n))$, $O(n \log^i(n))$

Counter examples: $O(n^{1,0001})$, $O(n\sqrt{n})$

Scheme of proof

We use :

- A new Hanf normal form for FO queries.¹
To shape every query into local queries.
- The algorithm for the model checking.²
For the base case of the induction.
- Game characterization of nowhere dense classes.²
Gives us an inductive parameter.
- Neighbourhood cover.²
- Short-cut pointers dedicated to the enumeration.³

³Segoufin, Vigny '17

Neighborhood cover

A neighborhood cover is a set of “representative” neighborhoods.

$\mathcal{X} := X_1, \dots, X_n$ is a r -neighborhood cover if it has the following properties:

- $\forall a \in G, \exists X \in \mathcal{X}, N_r(a) \subseteq X$
- $\forall X \in \mathcal{X}, \exists a \in G, X \subseteq N_{2r}(a)$
- the degree of the cover is: $\max_{a \in G} |\{i \mid a \in X_i\}|$.

Theorem: Grohe, Kreutzer, Siebertz '14

Over nowhere dense classes, for every r and ϵ , an r -neighborhood cover of degree $|G|^\epsilon$ can be computed in time $O(|G|^{1+\epsilon})$.

The examples queries

$$\rightarrow q_1(x, y) := \exists z E(x, z) \wedge E(z, y)$$

(The distance two query)

$$\rightarrow q_2(x, y) := \neg q_1(x, y)$$

(Nodes that are far apart)

How to use the game 1/2

G is now fixed

Goal : Given a node a we want to enumerate all b such that $q_1(a, b)$.
(Here $r = 4$)

- Base case: If Splitter wins the $(1, r)$ -Splitter game on G .
Then G is edgeless and there is no solution!
- By induction: assume that there is an algorithm for every G' such that Splitter wins the (ℓ, r) -Splitter game on G' .

How to use the game 2/2

Here, Splitter wins the $(\ell+1, r)$ -game on G .

Idea :

- Compute some new graph on which Splitter wins the (ℓ, r) game.
- Alter the query and apply the algorithm given by induction.
The solutions for the old query on the old graph and for the new query on the new graph must be the same.
- Enumerate those solutions.

How to use the game 2/2

Here, Splitter wins the $(\ell+1, r)$ -game on G .

Idea :

- Compute some new graph on which Splitter wins the (ℓ, r) game.
- Alter the query and apply the algorithm given by induction.
The solutions for the old query on the old graph and for the new query on the new graph must be the same.
- Enumerate those solutions.

The new graph is a bag of the neighborhood cover.

For every $(a, b) \in G^2$ we have:

$$G \models q_1(a, b) \iff \bigvee_{X \in \mathcal{X}} X \models q_1(a, b) \iff \mathcal{X}(a) \models q_1(a, b)$$

How to use the game 2/2

Here, Splitter wins the $(\ell+1, r)$ -game on G .

Idea :

- Compute some new graph on which Splitter wins the (ℓ, r) game.
- Alter the query and apply the algorithm given by induction.
The solutions for the old query on the old graph and for the new query on the new graph must be the same.
- Enumerate those solutions.

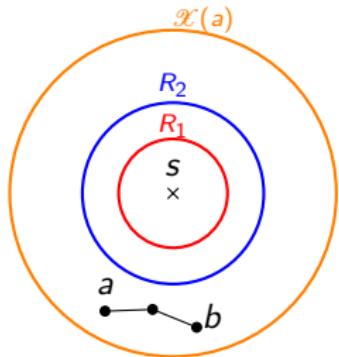

The new graph is a bag of the neighborhood cover.

For every $(a, b) \in G^2$ we have:

$$G \models q_1(a, b) \iff \bigvee_{X \in \mathcal{X}} X \models q_1(a, b) \iff \mathcal{X}(a) \models q_1(a, b)$$

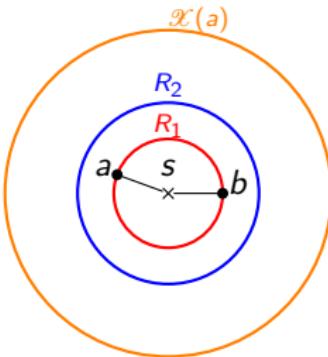

The new graph is $\mathcal{X}(a)$
Then, Splitter deletes a node!

The new queries

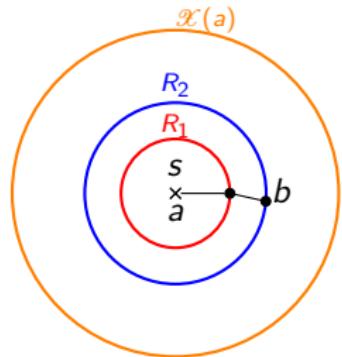

when there is still a
2-path not using s

the new query is:
 $q_1(x, y)$

when s is on the only
short path from a to b

the new query is:
 $R_1(x) \wedge R_1(y)$

when $a = s$
(similarly for $b = s$)

the new query is:
 $R_2(y)$

Running time

Without using the cover

- To each a , associate $N_r^G(a) \setminus s_a$.
- For every such graphs, compute the preprocessing given by induction.

Total running time: $\sum_{a \in G} (|N_r^G(a) \setminus s_a|) = O(|G|^2)$.

Using the cover

- To each a , associate an $X \in \mathcal{X}$ such that $N_r^G(a) \subseteq X$.
- To each X , associate the answer s_X of Splitter.
- For every $X \setminus s_X$, compute the preprocessing given by induction.

Total running time: $\sum_{X \in \mathcal{X}} (|X \setminus s_X|) = O(|G|^{1+\epsilon})$

The second query

$$q_2(x, y) := \text{dist}(x, y) > 2$$

Two kinds of solutions:

$b \in \mathcal{X}(a)$ (similar to the previous example)

$b \notin \mathcal{X}(a)$ We need something else !

Recap

Theorem: Schweikardt, Segoufin, Vigny (PODS '18)

Over *nowhere dense* classes of graphs, for every FO query, after a *pseudo-linear* preprocessing, we can:

- **enumerate** every solution with constant delay.
- **test** whether a given tuple is a solution in constant time.

Theorem: Grohe, Schweikardt (alternative proof, Vigny)

Over *nowhere dense* classes of graphs, for every FO query, we can **count** the number of solutions in *pseudo-linear* time.

Complexity

Pseudo-linear preprocessing: $O(f(|q|) \times |G|^{1+\epsilon})$

But $f(\cdot)$ is a non-elementary function.

New directions

1) Classes of graphs that are not closed under subgraphs.

The dichotomy only holds for classes of graphs that are
closed under subgraphs.

Existing results for interpretations of classes of graphs with:

- bounded degree¹
- bounded expansion²

What about nowhere dense ?

New directions

2) Enumeration with update.

What happens if a small change occurs after the preprocessing?

Can we change the index accordingly?
In constant time? In logarithmic time?

Existing results for: words,^{1,2} graphs with bounded degree³ and ACQ.⁴

New directions

3) Implementable scenarios.

In general the constants factors are a tower of exponentials.

Can they be polynomial? Or even linear?

Existing results for: Document Spanners,^{1,2} and one class of graphs for conjunctive queries.³
